1 Introduction

In addition to Resources Selection Functions (RSF) a more detailed analysis for telemetry data can be conducted by using Step Selection Function (SSF). The use of latter is providing answers to the actual selection of animals on their habitat rather than analysing the use of a habitat only. (DO WE WANT TO CITE, HERE FOR EXAMPLE Simone and friends). So far most of the SSF were done in GIS to use spatial data together with mathematics equations. However, more and more packages are provided in R and thus becomes a valuable alternative. This tutorial provides an overview on how to implement SSF with R. The main package we will use in the following is the package **adehabitatLT**. All single steps that need to be taken care of are summarized in (Figure 1). In our tutorial we use telemetry data from Cougars/Mountain Lion (*Latin name*) collected by Simone Ciuti¹. As spatial parameters x tables for ruggedness, slope, canopy cover etc. are available. Describe study area...

$$w(x) = \exp(\beta x_1 + \beta x_2 + \dots + \beta x_n)$$

Why did we not use the data (Wildboar) prepared for the **adehabitatLT** package? - No information on details, metadata provided, it is hard to understand when to use which dataset and why.

2 Preparations

Before you can actually start using the tutorial for conducting SSF you need to load a bunch of packages in R. Some of them require others so that you have to add all these to your library:

2.1 Packages - what we need

```
# installing packages -----
## for implementing SSF
# install.packages("adehabitat") # outdated version, not needed for this tutorial
install.packages("adehabitatHR")
install.packages("adehabitatHS")
install.packages("adehabitatLT")
install.packages("adehabitatMA")
install.packages("tkrplot")
install.packages("hab", repos = "http://ase-research.org/R/") # regular
install.packages("hab", repos = "http://ase-research.org/R/", type = "source") # for source

# for handling raster data
install.packages("move")
install.packages("raster")
install.packages("rgdal")
#install.packages("")

# loading the packages
# require(adehabitat) # keep fingers off this package. It is outdated.
require(hab)
require(adehabitatMA)
require(adehabitatHR)
require(adehabitatHS)
```

¹we might have to specify that and name and thank the institute.../collected/containing

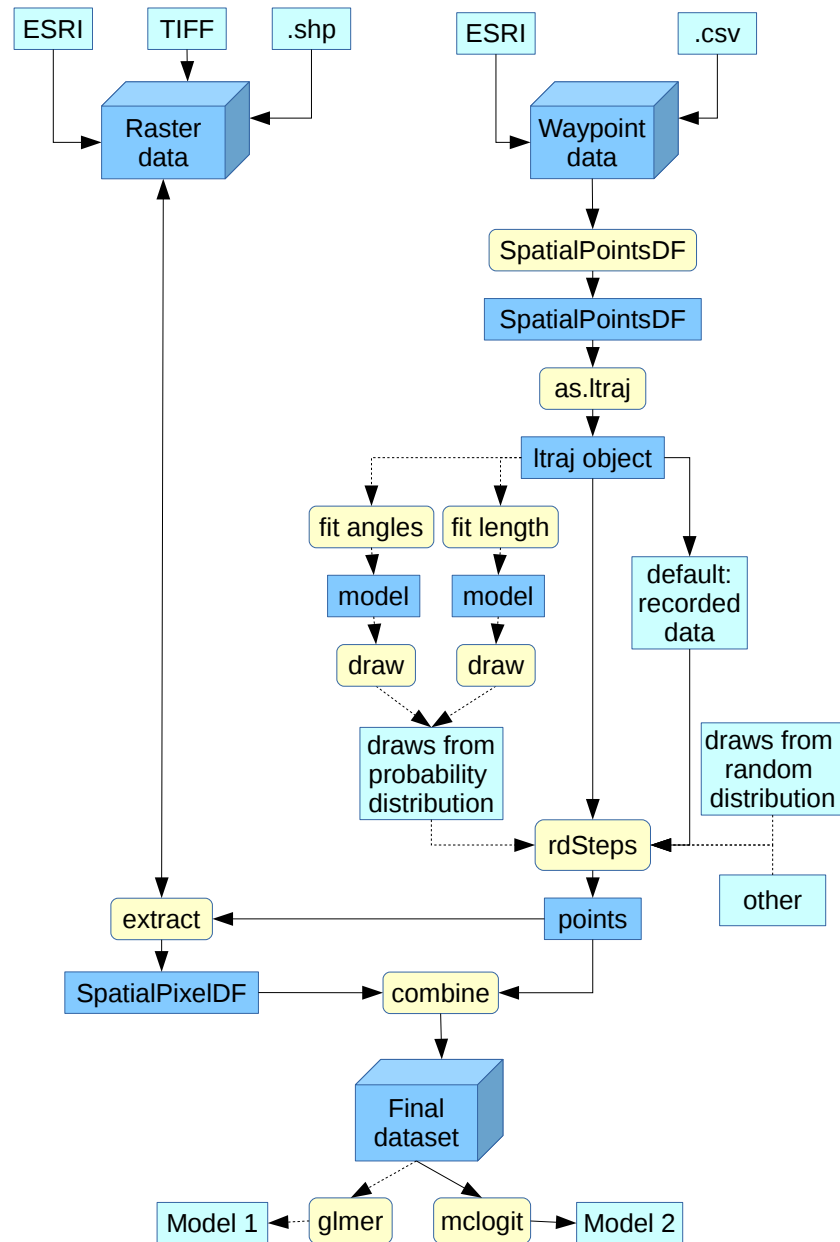

Figure 1: *Conducting a SSF using existing R-packages*: this figures provides an overview of the steps necessary to conduct a SSF. The steps are separated in subsections, which the turtorial will guide you through.

```
require(adehabitatLT)

## for i dont know

#require(move)
#require(raster)
#require(rgdal)
#require(tkrplot)
#require(raster)
#require(sp)
```

3 Loading telemetry data (*.csv, ESRI)

The data for the analysis should be saved in a simple *.csv file format. The table should have column headings in the first line and for each observation include at least the following values:

1. x-coordinate (easting)
2. y-coordinate (northing)
3. date and/or time
4. animal ID

Note that the coordinates need to be provided in the same coordinate system and spatial projection as the raster data.

Depending on your analysis you can include further values such as:

1. ID for each record
2. GPS precision
3. other recording parameters such as season
4. temperature / elevation at the moment of record
5. other values that might be of interest in the further analysis

Use the following commands to set your working directory and read the data:

```
setwd("/your/working/directory")
xmpl = read.csv("xmpl.csv", head=T)
```

You can execute `head(xmpl)` and `str(xmpl)` to check, whether the data were successfully read.

4 Creating a Spatial Points Data Frame

The functions used along the rest of the toolchain can only process data that are stored as objects of class "SpatialPointsDataFrame". This object class stores the coordinates separately and can be created using the according function from package "sp".

```
require(sp)

xmpl.spdf = SpatialPointsDataFrame(coords = xmpl[,c("easting", "northing")], data = xmpl[,
names(xmpl)
```

In the "coords" argument of the function you should specify the coordinate vectors for your dataset. In our example, we simply assign the two coordinate columns of the example dataset, but you can read the coordinates from a separate file if you want.

5 Creating an ltraj object

After storing the data in a Spatial Points Data Frame, you now need to connect the single points and turn them into a set of trajectories. This operation is carried out by the function `as.ltraj` from the "hab" package and produces objects of class "ltraj". The function `as.ltraj` requires at least three arguments to work:

1. "xy" (x- and y- coordinates for each point)
2. "date" (timestamp for each point, given as POSIXct class)
3. "id" (the animal id)

Both coordinates and animal id can easily be adopted from the Spatial Points Data Frame. The timestamp however, is not stored in the required format yet and you therefore need to convert it first:

```
date <- as.POSIXct(strptime(paste(xmpl.spdf$LMT_DATE, xmpl.spdf$LMT_TIME), "%d/%m/%Y %H:%M:%S"))
```

It is necessary to combine date and time in one POSIXct value. If your dataset already features a POSIXct timestamp, you can skip this step.

Now you can proceed and actually create the ltraj object by executing the following command:

```
xmpl.ltr <- hab:::as.ltraj(xy = xmpl.spdf@coords, date = date, id = xmpl.spdf$cat)
```

Two comments to the function as used: By typing `hab:::as.ltraj` you tell R to use the `as.ltraj` function from the "hab" package which is speed optimized against its "adehabitatLT" sibling. Unlike the `xmpl.spdf@coords` prompt which works for any SPDF object, the `xmpl.spdf$cat` prompt is specific to your dataset. In the example dataset, animal ID's are stored as an integer.

You now may want to have a closer look at the created ltraj object. Display its structure with by executing `str(xmpl.ltr)`.

```
str(xmpl.ltr)
```

When scrolling through the output you will first notice that it consists of 7 elements - the number of individuals in the example dataset. This is because `as.ltraj()` automatically splits the dataset into subsets one for each individual. We will refine these subsets in the next chapter. Furthermore, the ltraj contains information on the distances and turning angles between consecutive locations. To get a visual impression of your data you can plot the trajectory for all or for one particular animal:

```
plot(xmpl.ltr)
unique(xmpl.spdf$cat) # prompts a list of all cat ID's. Choose one that you are intere
plot(xmpl.ltr, id=10289)
```

6 Creating bursts

7 Compute random steps

The function `rdSteps` removes the first and the last data point. That's what you want.

8 Spatial covariates

This section explains the handling of spatial parameters that will be tested for selection by the target species. You should store these data in raster files (ESRI *.adf or georeferenced *.tif). These should have the same coordinate system as your telemetry data and should (for time reasons) already be clipped to your study area and. For instructions how to do this in R, please read the GIS instructions from the other group ;)

8.1 Load raster data (ESRI, *.tif, (*.shp))

With a simple function stored in the package `raster` you are able to upload any raster file into R. Exemplarily we use raster data on the following parameters for the study area:

1. ruggedness of the terrain
2. land cover
3. canopy cover
4. distance to the nearest highway
5. distance to the nearest road

```
require(raster)
require(rgdal)

require(sp)

#?raster
#getwd()
#setwd("/home/Peter/")

ruggedness <- raster("/home/Peter/Dokumente/uni/WS_14_15/Best Practice R/Dataset/NEW GIS
# plot(ruggedness) # outcomment this if you just quickly want to run the script. Takes

landcover <- raster("/home/Peter/Dokumente/uni/WS_14_15/Best Practice R/Dataset/NEW GIS
# plot(landcover) # outcomment this if you just quickly want to run the script. Takes
```

```

canopycover <- raster("/home/Peter/Dokumente/uni/WS_14_15/Best Practice R/Dataset/NEW GIS
# plot(canopycover) # uncomment this if you just quickly want to run the script. Takes a m

disthighway <- raster("/home/Peter/Dokumente/uni/WS_14_15/Best Practice R/Dataset/NEW GIS
# plot(disthighway) # uncomment this if you just quickly want to run the script. Takes a m

distroad <- raster("/home/Peter/Dokumente/uni/WS_14_15/Best Practice R/Dataset/NEW GIS
plot(distroad) # uncomment this if you just quickly want to run the script. Takes a m

```

```

# Raster extraction -----

#sp <- SpatialPoints(xy)
# cougarsRugged <- extract(ruggedness, cougarsSPDF, method='simple', sp=T, df=T)
# method = 'bilinear' interpolates values from four nearest cells. sp returns Spatial

# first convert the cougars.steps into a SpatialPointsDataFrame

#cougars.steps.SPDF = SpatialPointsDataFrame(coords = cougars.steps[,c("new_x", "new_y"),
cougars.steps.c.SPDF = SpatialPointsDataFrame(coords = cougars.steps.c[,c("new_x", "new_y"),

#cougars.steps.Rugged <- extract(ruggedness, cougars.steps.SPDF, method='simple', sp=T, df=T)
#cougars.steps.c.Rugged <- extract(ruggedness, cougars.steps.c.SPDF, method='simple', sp=T, df=T)

# method = 'simple' extracts value from nearest cell. method = 'bilinear' interpolates values from four nearest cells.

ruggedness.extr <- extract(ruggedness, cougars.steps.c.SPDF, method='simple', sp=F, df=T)
landcover.extr <- extract(landcover, cougars.steps.c.SPDF, method='simple', sp=F, df=T)
canopycover.extr <- extract(canopycover, cougars.steps.c.SPDF, method='simple', sp=F, df=T)
disthighway.extr <- extract(disthighway, cougars.steps.c.SPDF, method='simple', sp=F, df=T)
distroad.extr <- extract(distroad, cougars.steps.c.SPDF, method='simple', sp=F, df=T)

cougars.steps.c.SPDF$ruggedness <- ruggedness.extr[,2]
#cougars.steps.c.SPDF$landcover <- landcover.extr[,2]
cougars.steps.c.SPDF$landcover1 <- as.factor(
  ifelse(landcover.extr[,2] == 0, "NA",
  ifelse(landcover.extr[,2] < 5, "forest",
  ifelse(landcover.extr[,2] < 8, "open", "NA"))))
cougars.steps.c.SPDF$canopycover <- canopycover.extr[,2]
cougars.steps.c.SPDF$disthighway <- disthighway.extr[,2]
cougars.steps.c.SPDF$distroad <- distroad.extr[,2]

head(cougars.steps.c.SPDF)

#head(cougars.steps.Rugged)
#View(cougars.steps.Rugged)

```

```
#head(cougars.steps.c.Rugged)  
#View(cougars.steps.c.Rugged)  
  
#names(ruggedness)  
#head(cougars)  
#head(cougarsRugged)
```

8.2 Extract coordinates for comparison of used and random points

Peter is successfully doing this step!!

9 Final SSF model
